

# A Simple Introduction to Syndrome-Decoding- Based Cryptography

**Paulo S. L. M. Barreto**

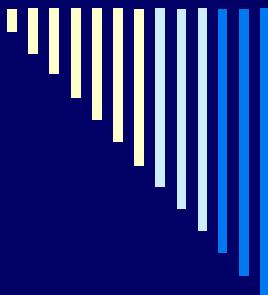

# Contents

- Motivation and basic concepts of error-correcting codes
- Cryptosystems based on syndrome decoding (McEliece and Niederreiter encryption, CFS signatures)
- Constructing and decoding Goppa codes
- Current challenges (reducing key sizes, safe codes, new functionality)

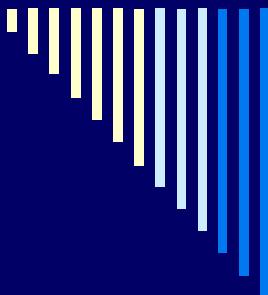

# Motivation

# Deployed Cryptosystems

- Conventional intractability assumptions:
  - Integer Factorization (IFP): RSA.
  - Discrete Logarithm (DLP), Diffie-Hellman (DHP), bilinear variants: ECC, PBC.
- These assumptions reduce to the *Hidden Subgroup Problem* – HSP.

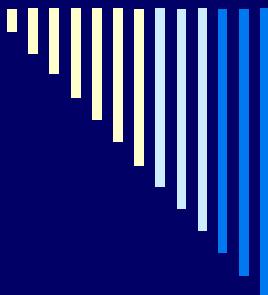

# Quantum Computing

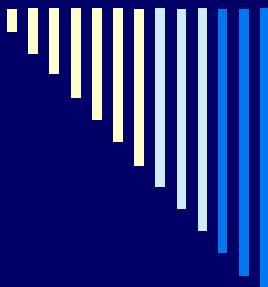

- Shor's quantum algorithm can solve particular cases of the AHSP (including IFP and DLP) in random polynomial time.

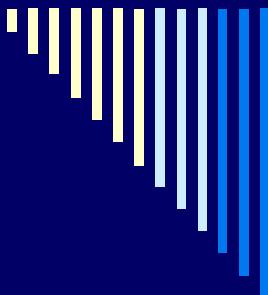

# Proposed Post-Quantum Cryptosystems

- Quantum computers seem to be unable to solve NP-complete/NP-hard problems.
- Syndrome Decoding (this seminar)
- Lattice Reduction
- Merkle signatures, Multivariate Quadratic Systems, Non-Abelian (e.g. Braid) Groups, Permuted Kernels and Perceptrons, Constrained Linear Equations...

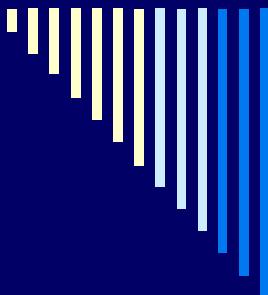

# Basic Concepts of Error-Correcting Codes

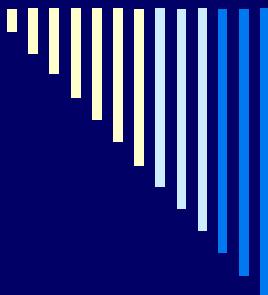

# Linear Codes

- The (Hamming) *weight*  $w(u)$  of  $u \in (\mathbb{F}_q)^n$  is the number of nonzero components of  $u$ , and the (Hamming) distance between  $u, v \in (\mathbb{F}_q)^n$  is  $\text{dist}(u, v) \equiv w(u - v)$ .
- A linear  $[n, k]$ -code  $\mathcal{C}$  over  $\mathbb{F}_q$  is a  $k$ -dimensional vector subspace of  $(\mathbb{F}_q)^n$ .

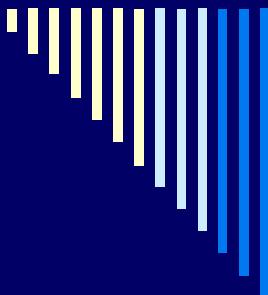

# Linear Codes

- A code may be defined by a *generator* matrix  $G \in (\mathbb{F}_q)^{k \times n}$  or by a *parity-check* matrix  $H \in (\mathbb{F}_q)^{r \times n}$  with  $r = n - k$ .
  - $\mathcal{C} = \{ uG \in (\mathbb{F}_q)^n \mid u \in (\mathbb{F}_q)^k \}$
  - $\mathcal{C} = \{ v \in (\mathbb{F}_q)^n \mid Hv^T = 0^r \}$
- N.B. The vector  $s$  such that  $Hv^T = s^T$  is called the *syndrome* of  $v$ .
- N.B.  $HG^T = O$ .

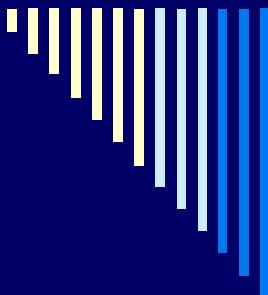

# Linear Codes

- Generator and parity-check matrices are not unique: given an arbitrary nonsingular matrix  $S \in (\mathbb{F}_q)^{k \times k}$  (resp.  $S \in (\mathbb{F}_q)^{r \times r}$ ), the matrix  $G' = SG$  (resp.  $H' = SH$ ) defines the same code as  $G$  (resp.  $H$ ) in another basis.
- Consequence: systematic (echelon) form  $G = [I_k \mid M]$ ,  $H = [-M^\top \mid I_r]$  where  $M \in (\mathbb{F}_q)^{k \times r}$ . N.B.: not always possible.

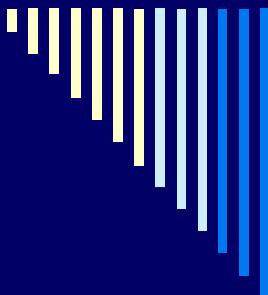

# Linear Codes

- Two codes are (permutation) *equivalent* if they differ essentially by a permutation on the coordinates of their elements.
- Formally, a code  $\mathcal{C}'$  generated by  $G'$  is equivalent to a code  $\mathcal{C}$  generated by  $G$  iff  $G' = SGP$  for some permutation matrix  $P \in (\mathbb{F}_q)^{n \times n}$  and some nonsingular matrix  $S \in (\mathbb{F}_q)^{k \times k}$ . Notation:  $\mathcal{C}' = \mathcal{C}P$ .

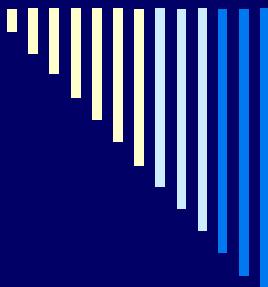

# General Decoding

- **Input:** positive integers  $n, k, t$ ; a finite field  $\mathbb{F}_q$ ; a linear  $[n, k]$ -code  $\mathcal{C} \in (\mathbb{F}_q)^n$  defined by a generator matrix  $G \in (\mathbb{F}_q)^{k \times n}$ ; a vector  $c \in (\mathbb{F}_q)^n$ .
- **Question:** is there a vector  $m \in (\mathbb{F}_q)^k$  s.t.  $e = c - mG$  has weight  $w(e) \leq t$ ?
- NP-complete!
- **Search:** find such a vector  $e$ .

# Syndrome Decoding

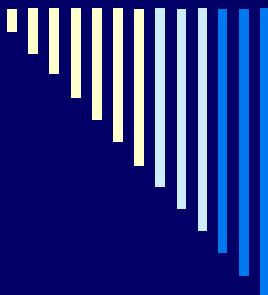

- **Input:** positive integers  $n, k, t$ ; a finite field  $\mathbb{F}_q$ ; a linear  $[n, k]$ -code  $\mathcal{C} \in (\mathbb{F}_q)^n$  defined by a parity-check matrix  $H \in (\mathbb{F}_q)^{r \times n}$  with  $r = n - k$ ; a vector  $s \in (\mathbb{F}_q)^r$ .
- **Question:** is there a vector  $e \in (\mathbb{F}_q)^n$  of weight  $w(e) \leq t$  s.t.  $He^T = s^T$ ?
- NP-complete!
- **Search:** find such a vector  $e$ .

# Easily Decodable Codes

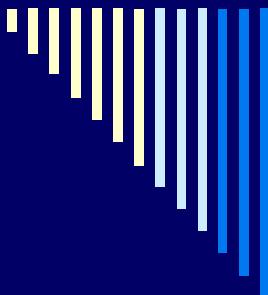

- Some codes allow for efficient decoding, e.g. GRS/alternant codes with a parity-check matrix of form  $H = VD$  with

$$V = \begin{bmatrix} 1 & 1 & \dots & 1 \\ L_0 & L_1 & \dots & L_{n-1} \\ L_0^2 & L_1^2 & \dots & L_{n-1}^2 \\ \vdots & \vdots & \ddots & \vdots \\ L_0^{r-1} & L_1^{r-1} & \dots & L_{n-1}^{r-1} \end{bmatrix}, D = \begin{bmatrix} D_0 & 0 & 0 & \dots & 0 \\ 0 & D_1 & 0 & \dots & 0 \\ 0 & 0 & D_2 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & D_{n-1} \end{bmatrix}.$$

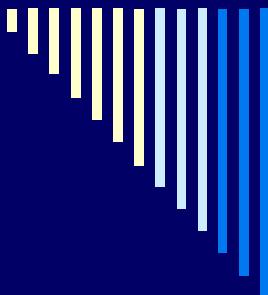

# Easily Decodable Codes

- N.B. The decoding algorithm may require a syndrome computed with such a special parity-check matrix  $H$ .
- Given a syndrome  $c^T = Au^T$  computed with a different parity-check matrix  $A$  for the same code (hence  $H = SA$  for some  $S$ ), a decodable syndrome is obtained as  $s^T = Sc^T = Hu^T$  with  $S = HA^T(AA^T)^{-1}$ .

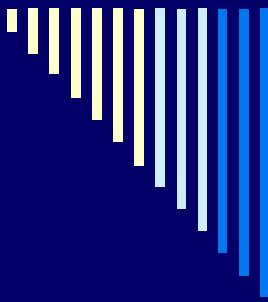

# Permuted Decoding

- **Problem:** Solve the GDP/SDP for a code  $\mathcal{C}$  that is permutation equivalent to some efficiently decodable code  $\mathcal{C}'$ .
- Obvious resolution strategy: find the permutation and basis change between the codes, and use the  $\mathcal{C}'$  trapdoor to decode in  $\mathcal{C}$ .
- Conjectured to be “hard enough” for certain codes.

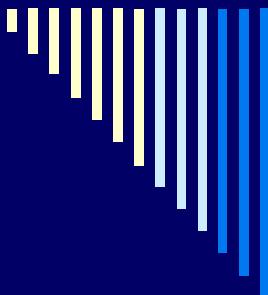

# Shortened Decoding

- **Problem:** Solve the GDP/SDP for a code  $\mathcal{C}$  that is permutation equivalent to some shortened (i.e. projection) subcode of some efficiently decodable code  $\mathcal{C}'$ .
- Obvious resolution strategy: find the permutation, basis change and shortening between the codes, and use the  $\mathcal{C}'$  trapdoor to decode in  $\mathcal{C}$ .
- Deciding whether a code is equivalent to a shortened code is NP-complete.

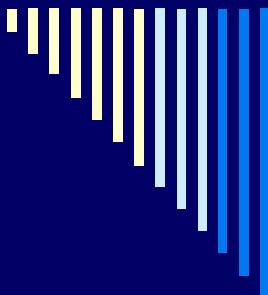

# Cryptosystems Based on Syndrome Decoding

# McEliece Cryptosystem

- Key generation:
  - Choose a uniformly random  $[n, k]$   $t$ -error correcting, efficiently decodable code  $\Gamma$  and a uniformly random permutation matrix  $P \in (\mathbb{F}_q)^{k \times k}$ , and compute a systematic generator matrix  $G \in (\mathbb{F}_q)^{k \times n}$  for the equivalent code  $\Gamma P$ .
  - Set  $K_{\text{priv}} = (\Gamma, P)$ ,  $K_{\text{pub}} = (G, t)$ .
- Encryption of a plaintext  $m \in (\mathbb{F}_q)^k$ :
  - Choose a uniformly random  $t$ -error vector  $e \in (\mathbb{F}_q)^n$  and compute  $c = mG + e \in (\mathbb{F}_q)^n$ .
- Decryption of a ciphertext  $c \in (\mathbb{F}_q)^n$ :
  - Correct the errors in  $c' = cP^{-1}$ , i.e. find the  $t$ -error vector  $e' = eP^{-1}$  s.t.  $c' - e' \in \Gamma$ , then recover  $m$  directly from  $c - e \in \Gamma P$ .

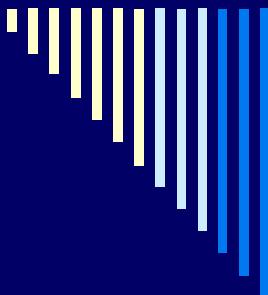

# A Toy Example

- Let  $n = 8$ ,  $t = 1$ ,  $k = 4$ , and a code with the following systematic parity-check matrix  $H$  and generator matrix  $G$ :

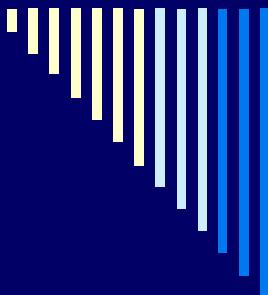

$$H = \left[ \begin{array}{cccc|cccc} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 \end{array} \right], \quad G = \left[ \begin{array}{cccc|cccc} 1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 0 & 1 & 1 \end{array} \right].$$

- Encryption of the message  $m = (1\ 1\ 0\ 0)$  with error vector  $e = (0\ 0\ 1\ 0\ 0\ 0\ 0\ 0)$ :  $c = mG + e = (1\ 1\ 1\ 0\ 0\ 1\ 0\ 1)$ .
- Syndrome computation  $Hc^T = (1\ 1\ 1\ 1)^T$ , error correction reveals  $e$  and yields  $mG = c - e = (\underline{\underline{1\ 1\ 0\ 0}})0\ 1\ 0\ 1$ .

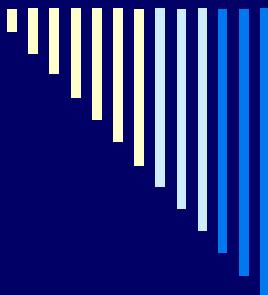

# Niederreiter Cryptosystem

- Key generation:
  - Choose a uniformly random  $[n, k]$   $t$ -error correcting, efficiently decodable code  $\Gamma$  and a uniformly random permutation matrix  $P \in (\mathbb{F}_q)^{k \times k}$ , and compute a systematic parity-check matrix  $H \in (\mathbb{F}_q)^{r \times n}$  for the equivalent code  $\Gamma P$ .
  - Set  $K_{\text{priv}} = (\Gamma, P)$ ,  $K_{\text{pub}} = (H, t)$ .
- Encryption of a plaintext  $m \in (\mathbb{F}_q)^\ell$  with  $\ell \leq (n \text{ choose } t)$ :
  - Represent  $m$  as a  $t$ -error vector  $e \in (\mathbb{F}_q)^n$ , and compute the syndrome  $c^T = He^T \in (\mathbb{F}_q)^r$ .
- Decryption of a ciphertext  $c \in (\mathbb{F}_q)^r$ :
  - Decode the syndrome  $c^T = He^T = (HP^{-1})(Pe^T) = (HP^{-1})(eP^{-1})^T$  to the error vector  $e' = eP^{-1}$  using the decoding algorithm for  $\Gamma$ , and obtain the plaintext  $m$  from  $e = e'P$ .

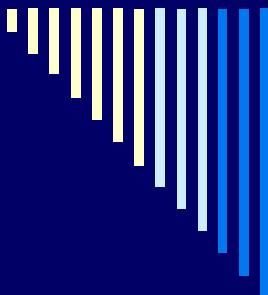

# CFS Signatures

- Key generation:
  - Choose a uniformly random  $[n, k]$   $t$ -error correcting, efficiently decodable code  $\Gamma$  and a uniformly random permutation matrix  $P \in (\mathbb{F}_2)^{k \times k}$ , and compute a systematic parity-check matrix  $H \in (\mathbb{F}_2)^{r \times n}$  for the equivalent code  $\Gamma P$ .
  - Choose a random oracle  $h: \{0, 1\}^* \times \mathbb{N} \rightarrow (\mathbb{F}_2)^r$ .
  - Set  $K_{\text{priv}} = (\Gamma, P)$ ,  $K_{\text{pub}} = (H, t)$ .
- Signing a message  $m$ :
  - Find  $i \in \mathbb{N}$  such that  $s \leftarrow h(m, i)$  is a decodable syndrome of  $\Gamma$ , i.e.  $s^\top = H e^\top = (H P^{-1})(e P^{-1})^\top$  for some  $t$ -error vector  $e P^{-1} \in (\mathbb{F}_q)^n$ .
  - Decode  $s^\top$  to the error vector  $e' = e P^{-1}$  using the decoding algorithm for  $\Gamma$ , and obtain  $e \leftarrow e' P$ . The signature is  $(e, i) \in (\mathbb{F}_2)^n \times \mathbb{N}$ .
- Verifying a signature  $(e, i)$ :
  - Check that  $w(e) \leq t$ , and compute  $c \leftarrow H e^\top$ .
  - Accept the signature iff  $c = h(m, i)$ .

# IND-CCA2 Security

- McEliece is not secure in the strong sense of indistinguishability under an adaptive chosen-ciphertext attack (e.g.  $c = mG + e$  reveals all bits of  $m$  but  $t$ , at most).
- Solution: all-or-nothing transform (AONT), e.g. (McEliece-tailored) Fujisaki-Okamoto.

# IND-CCA2 Security

## □ Random oracles

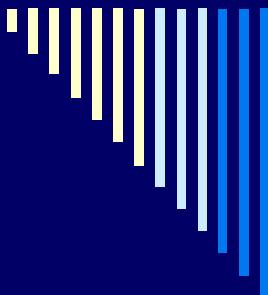

- $\mathcal{R}: (\mathbb{F}_2)^k \rightarrow \{0, 1\}^*$ .
- $\mathcal{H}: (\mathbb{F}_2)^k \times \{0, 1\}^* \rightarrow \{0, \dots, \binom{n}{t} - 1\}$ , with output encoded as a vector in  $(\mathbb{F}_2)^n$ .

## □ Encryption of $m \in \{0, 1\}^*$ :

- $u \leftarrow$  random  $(\mathbb{F}_2)^k$
- $c \leftarrow \mathcal{R}(u) \oplus m$
- $e \leftarrow \mathcal{H}(u, m)$
- $z \leftarrow uG + e$

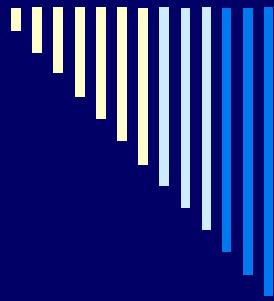

□ The ciphertext is  $(z, c) \in (\mathbb{F}_2)^n \times \{0, 1\}^*$ .

□ Decryption: find  $u$  and  $e$  from  $z$ , recover  $m \leftarrow \mathcal{R}(u) \oplus c$ , and accept iff  $e = \mathcal{H}(u, m)$ .

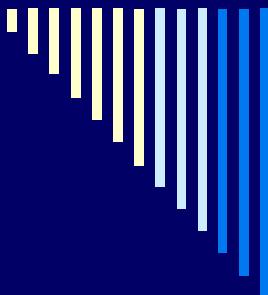

# Summary

- Syndrome decoding based cryptosystems are simple and efficient.
- Security related to NP-complete and NP-hard problems (a suitable code may make this relation stronger).
- Strong notions of security are possible in the RO model using a suitable AONT.

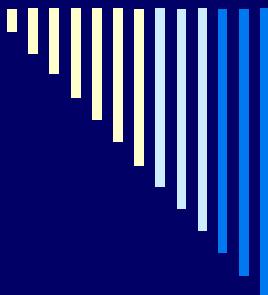

# Goppa Codes

# Goppa Codes

- Let  $g(x) = \sum_{i=0}^t g_i x^i$  be a monic ( $g_t = 1$ ) polynomial in  $\mathbb{F}_q[x]$  where  $q = p^m$ .
- Let  $L = (L_0, \dots, L_{n-1}) \in (\mathbb{F}_q)^n$  (all distinct) such that  $g(L_j) \neq 0$  for all  $j$ .  $L$  is called the code support.
- Properties:
  - Easy to generate and plentiful.
  - Usually  $g(x)$  is chosen to be irreducible; if so,  $\mathbb{F}_{q^t} = \mathbb{F}[x]/g(x)$ .

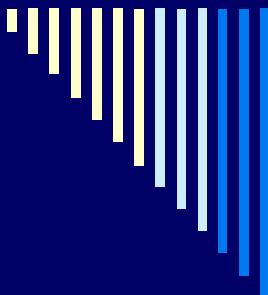

# Goppa Codes

- The *syndrome function* is the linear map  $S: (\mathbb{F}_p)^n \rightarrow \mathbb{F}_q[x]$ :

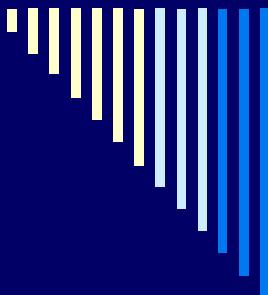

$$S(c) = \sum_{i=0}^{n-1} \frac{c_i}{x - L_i} = \sum_{i=1}^n \frac{1}{x - L_i} \pmod{g(x)}.$$

- The *Goppa code*  $\Gamma(L, g)$  is the kernel of the syndrome function, i.e.  $\Gamma = \{ c \in (\mathbb{F}_p)^n \mid S(c) = 0 \}$ .

# Goppa Codes

- The syndrome can be written in parity-check matrix form as  $H^* \in (\mathbb{F}_q)^{t \times n}$  or even  $H \in (\mathbb{F}_p)^{mt \times n}$ .
- Trace construction of the parity-check matrix  $H$ : write the  $\mathbb{F}_p$  components of each  $\mathbb{F}_q$  element (in a certain basis) from  $H^*$  on  $m$  successive rows of  $H$ .

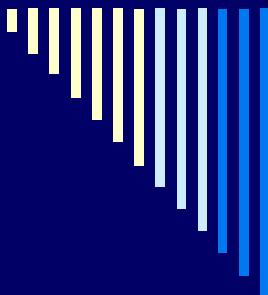

# Parity-Check Matrix

- Easy to compute  $H^*$  from  $L$  and  $g$ , namely,  $H^*_{t \times n} = T_{t \times t} V_{t \times n} D_{n \times n}$ , where:

$$T = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ g_{t-1} & 1 & 0 & \dots & 0 \\ g_{t-2} & g_{t-1} & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ g_1 & g_2 & g_3 & \dots & 1 \end{bmatrix}, \quad V = \begin{bmatrix} 1 & 1 & \dots & 1 \\ L_0 & L_1 & \dots & L_{n-1} \\ L_0^2 & L_1^2 & \dots & L_{n-1}^2 \\ \vdots & \vdots & \ddots & \vdots \\ L_0^{t-1} & L_1^{t-1} & \dots & L_{n-1}^{t-1} \end{bmatrix},$$

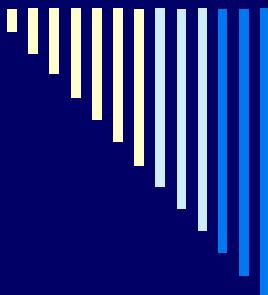

$$D = \begin{bmatrix} 1/g(L_0) & 0 & \dots & 0 \\ 0 & 1/g(L_1) & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1/g(L_{n-1}) \end{bmatrix}.$$

# A Toy Example

- The toy example sets  $m = 4$ ,  $\mathbb{F}_{2^m} = \mathbb{F}_2[u]/(u^4 + u + 1)$ ,  $n = 8$ ,  $t = 1$ ,  $k = n - mt = 4$ , with generator polynomial  $g(x) = x$  and support  $L = (u^7, u^2, u^3, u^{10}, u^{13}, u^1, u^{11}, u^0)$ .
- The parity-check matrix  $H^*$  (leading to the binary matrix  $H$  via the trace construction and systematic formatting) is

$$\begin{aligned} H^* &= TVD = \left[ \begin{array}{ccccccc} u^8 & u^{13} & u^{12} & u^5 & u^2 & u^{14} & u^4 & u^0 \end{array} \right], \\ T &= \left[ \begin{array}{c} 1 \end{array} \right], \\ V &= \left[ \begin{array}{ccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{array} \right], \\ D &= \text{diag} \left[ \begin{array}{cccc} 1/g(L_0) & 1/g(L_1) & \dots & 1/g(L_7) \end{array} \right]. \end{aligned}$$

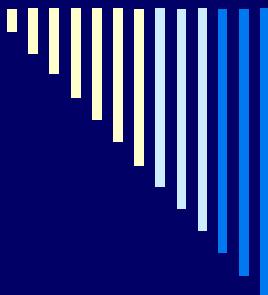

# Error Locator Polynomial

- Efficient decoding procedure for known  $g$  and  $L$  via the *error locator polynomial*.

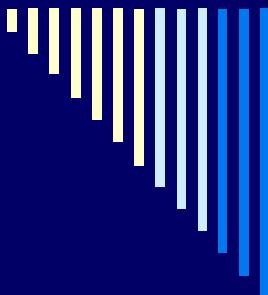

$$\sigma(x) \equiv \prod_{e_i \neq 0} (x - L_i) \in \mathbb{F}_q[x]/g(x).$$

- Property:  $\sigma(L_i) = 0 \Leftrightarrow e_i = 1$ .
- For simplicity, assume binary fields (otherwise an error evaluator polynomial must be defined and computed as well).

# Error Correction

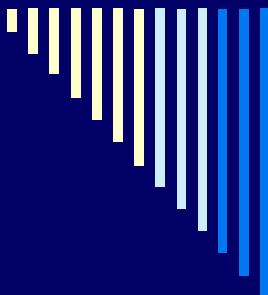

- Let  $m \in \Gamma$ , let  $e \in (\mathbb{F}_2)^n$  be an error vector of weight  $w(e) \leq t$ , and  $c = m + e$ :
  - Compute the syndrome of  $e$  through the relation  $S(e) = S(c)$ .
  - Compute the error locator polynomial  $\sigma$  from the syndrome.
  - Determine which  $L_i$  are zeroes of  $\sigma$  (Chien search) thus retrieving  $e$  and recovering  $m$ .

# Error Correction

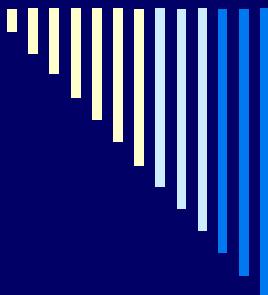

- Let  $s(x) \leftarrow S(e)$ . If  $s(x) \equiv 0$ , nothing to do (no error), otherwise  $s(x)$  is invertible.
  - Property #1:  $\sigma(x) = a(x)^2 + xb(x)^2$ .
  - Property #2:  $\frac{d}{dx}\sigma(x) = b(x)^2$ . (N.B.: char 2)
  - Property #3:  $\frac{d}{dx}\sigma(x) = \sigma(x)s(x)$ .
- Thus  $b(x)^2 = (a(x)^2 + xb(x)^2)s(x)$ , hence  
 $a(x) = b(x)v(x)$  with  $v(x) = \underbrace{\sqrt{x + 1/s(x)}}_{\text{Extended Euclid!}} \bmod g(x)$ .

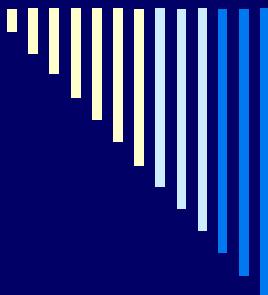

# A Toy Example

- The toy example sets  $g(x) = x$ ,  $L = (u^7, u^2, u^3, u^{10}, u^{13}, u^1, u^{11}, u^0)$ ,  $c = (1 \ 1 \ 1 \ 0 \ 0 \ 1 \ 0 \ 1)$ , and  $Hc^\top = (1 \ 1 \ 1 \ 1)^\top$ , so  $s(x) = u^3 + u^2 + u + 1 = u^{12}$ .
- Hence  $v(x) = (x + 1/s(x))^{1/2} \bmod g(x) = (x + u^3)^{1/2} \bmod x = (u^3)^{1/2} = u^9$ .
- Extended Euclid starts with  $a(x) = g(x) = x$  and  $b(x) = 0$ , and proceeds until  $\deg(a) \leq \lfloor t/2 \rfloor = 0$ ,  $\deg(b) \leq \lfloor (t-1)/2 \rfloor = 0$ , with  $a(x) = u^9$  and  $b(x) = 1$ .
- Thus  $\sigma(x) = x + u^3$ , which is zero for  $x = u^3 = L_2$ , and hence  $e_2 = 1$  (i.e.  $c_2$  is in error).

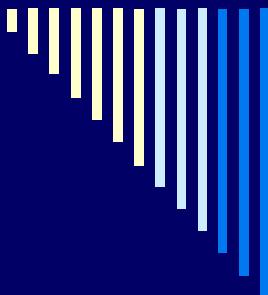

# Summary

- Goppa codes are simple to construct and to decode.
- Binary irreducible Goppa codes have distance  $2t + 1$ . The best one gets for any other alternant code is distance  $t + 1$ .
- Cryptosystems on Goppa codes remain unbroken.

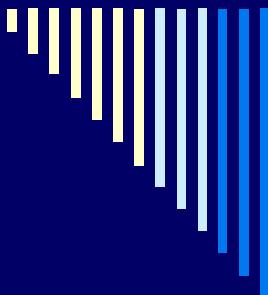

# Problems and Challenges

# Why Goppa?

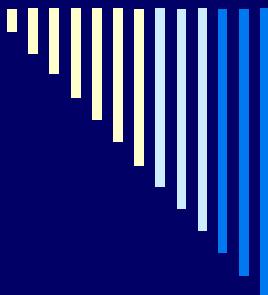

- Most syndrome-based cryptosystems can be instantiated with general  $[n, k]$ -codes, but not all choices of code are secure.
  - Gabidulin, maximum rank distance (MRD), GRS, low-density parity-check (LDPC) and several other codes are all insecure.
- Goppa seems to be OK.
  - Complexity of distinguishing a permuted Goppa code from a random code of the same length and distance:  $O(t n^{t-2} \log^2 n)$  [Sendrier 2000], or  $O(2^n/t)$  in most cryptosystems, where  $t = \Theta(n/\log n)$ .
  - Few known vulnerabilities (e.g. generator polynomial defined over a proper subfield of the base field).

# Choosing Parameters

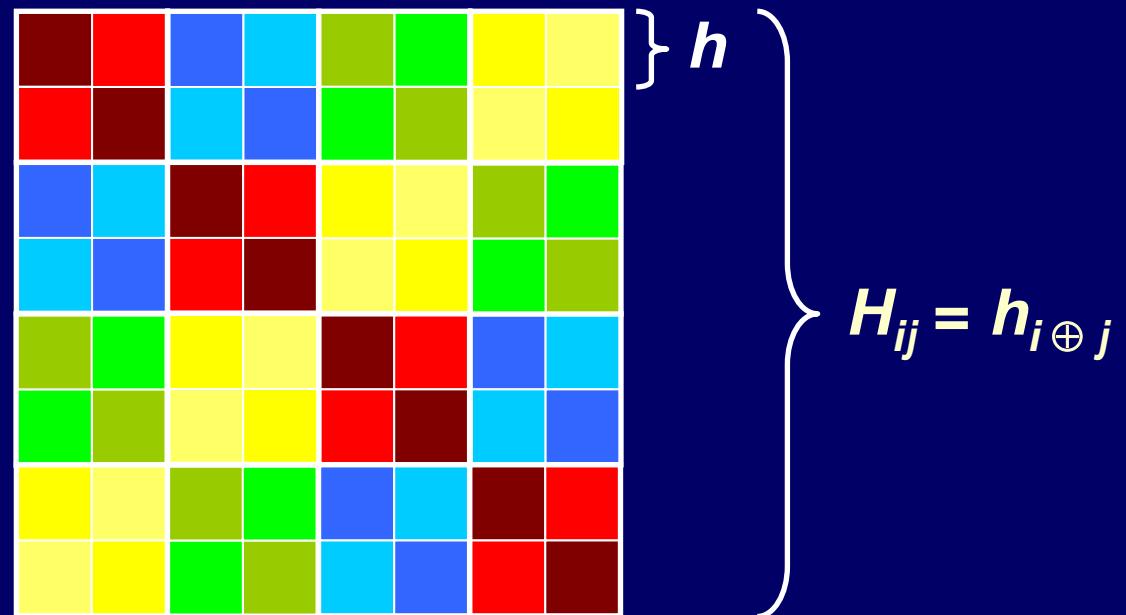

- Original McEliece setting:
  - $m = 10$ ,  $n = 2^m = 1024$  (hence  $L$  spans  $\mathbb{F}_{2^m}$ ),  $t = 50$ ,  
 $k = n - mt = 524$ , security  $\approx 2^{54}$ , naïve key size = 65.5 KiB, key size = 32 KiB.
- Other choices [BLP 2008]:

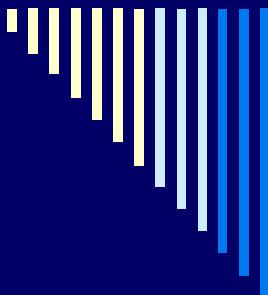

security	$n$	$t$	$k$	$m$	naïve key size	key size
$2^{80}$	1632	33+1	1269	11	74–253 KiB	57 KiB
$2^{128}$	2960	56+1	2288	12	243–827 KiB	188 KiB
$2^{192}$	4624	95+2	3389	13	698–1913 KiB	511 KiB
$2^{256}$	6624	115+2	5129	13	1209–4147 KiB	937 KiB

# Quasi-Dyadic Codes

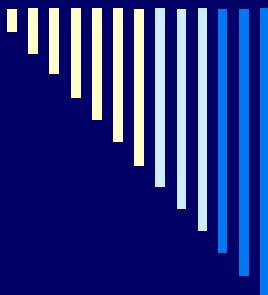

- Let  $t$  be a power of 2. A matrix  $H \in \mathcal{R}^{t \times t}$  over a ring  $\mathcal{R}$  is called *dyadic* iff  $H_{ij} = h_i \oplus_j$  for some vector  $h \in \mathcal{R}^t$ .

$$H_{ij} = h_i \oplus_j$$

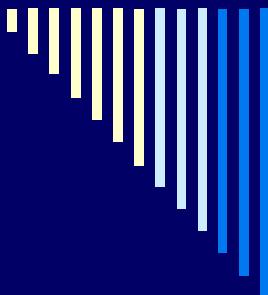

# Quasi-Dyadic Codes

- Dyadic matrices form a subring of  $\mathcal{R}^{t \times t}$  (commutative if  $\mathcal{R}$  is commutative).
- Compact:  $O(t)$  rather than  $O(t^2)$  space.
- Efficient: multiplication in time  $O(t \lg t)$  time via fast Walsh-Hadamard transform, inversion in time  $O(t)$  in characteristic 2.

# Quasi-Dyadic Codes

- A Cauchy matrix is a matrix  $C \in (\mathbb{F}_q)^{t \times n}$  where  $C_{ij} = 1/(z_i - L_j)$  for vectors  $z \in (\mathbb{F}_q)^t$  and  $L \in (\mathbb{F}_q)^n$ .
- Goppa codes admit a parity-check matrix in Cauchy form: just take  $z$  to be the roots of the generator polynomial, i.e.  $g(x) = (x - z_0) \dots (x - z_{t-1})$ .
- **Idea:** find a dyadic Cauchy matrix.

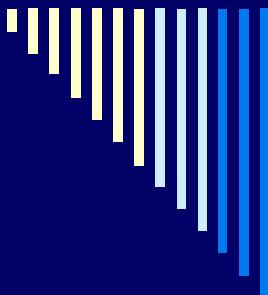

# Quasi-Dyadic Codes

- **Theorem:** a dyadic Cauchy matrix is only possible over fields of characteristic 2 (i.e.  $q = 2^m$  for some  $m$ ), and any suitable  $h \in (\mathbb{F}_q)^n$  satisfies

$$\frac{1}{h_{i \oplus j}} = \frac{1}{h_i} + \frac{1}{h_j} + \frac{1}{h_0}$$

with  $z_i = 1/h_i + \omega$ ,  $L_j = 1/h_j - 1/h_0 + \omega$  for arbitrary  $\omega$ , and  $H_{ij} = h_{i \oplus j} = 1/(z_i - L_j)$ .

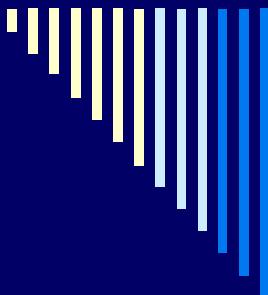

# Quasi-Dyadic Codes

- Choose distinct  $h_0$  and  $h_i$  with  $i = 2^u$  for  $0 \leq u < \lceil \lg n \rceil$  uniformly at random from  $\mathbb{F}_q$ , then set

$$h_{i+j} \leftarrow \frac{1}{\frac{1}{h_i} + \frac{1}{h_j} + \frac{1}{h_0}}$$

for  $0 < j < i$  (so that  $i + j = i \oplus j$ ).

- Complexity:  $O(n)$ .

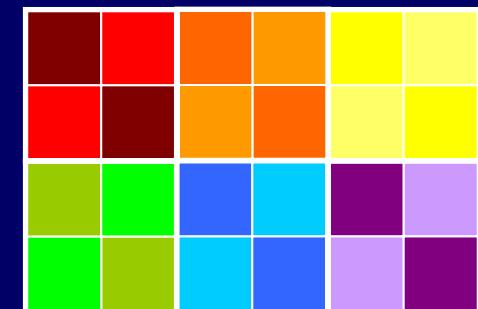

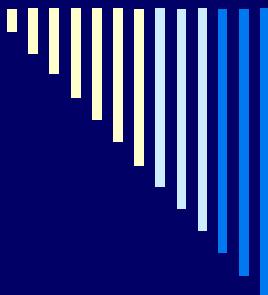

# Quasi-Dyadic Codes

## □ Structure hiding:

- choose a long dyadic code over  $\mathbb{F}_q$ ,
- blockwise shorten the code (Wieschebrink),
- permute dyadic block columns,
- dyadic-permute individual blocks,
- take a binary subfield subcode.

## □ Quasi-dyadic matrices: $((\mathbb{F}_2)^{t \times t})^{m \times \ell}$ .

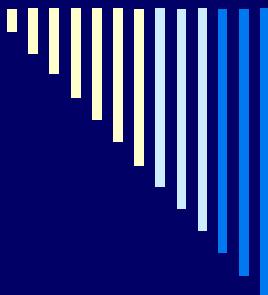

# Compact Keys

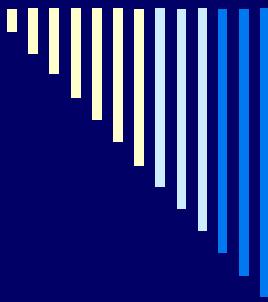

- Sample parameters for practical security levels (private codes over  $\mathbb{F}_{2^{16}}$ ).
- Still larger than RSA keys... but faster, and quantum-immune ☺

security	$n$	$t$	$k$	MB key size	BLP/MB
$2^{80}$	2304	64	1280	20480 bits	23
$2^{128}$	4096	128	2048	32768 bits	47
$2^{192}$	7168	256	3072	49152 bits	85
$2^{256}$	8192	256	4096	65536 bits	117

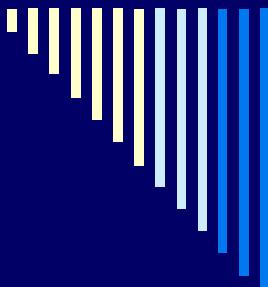

# Further Issues

- One can do encryption, signatures, even identity-based identification using ECC (error-correcting codes, not elliptic curve cryptosystems).
- How do we get identity-based encryption? What about other protocols that are easy with pairings? N.B. Some functionality is possible with lattices – why not with ECC?

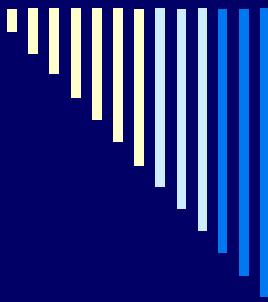

# Appendix A

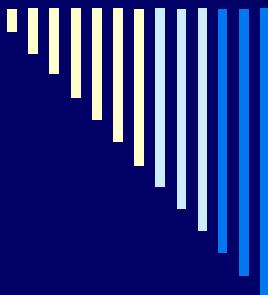

# Hidden Subgroup Problem

- Let  $\mathbb{G}$  be a group,  $\mathbb{H} \subset \mathbb{G}$ , and  $f$  a function on  $\mathbb{G}$ . We say that  $f$  separates cosets of  $\mathbb{H}$  if  $f(u) = f(v) \Leftrightarrow u\mathbb{H} = v\mathbb{H}, \forall u, v \in \mathbb{G}$ .
- Hidden Subgroup Problem (HSP):
  - Let  $\mathcal{A}$  be an oracle to compute a function that separates cosets of some subgroup  $\mathbb{H} \subset \mathbb{G}$ . Find a generating set for  $\mathbb{H}$  using information gained from  $\mathcal{A}$ .
- Important special cases:
  - Abelian Hidden Subgroup Problem (AHSP)
  - Dihedral Hidden Subgroup Problem (DHSP)

# Appendix B

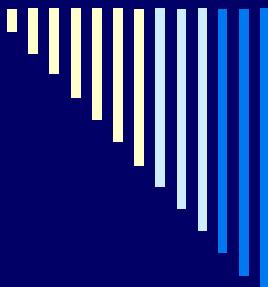

# Ranking and Unranking Permutations

- Let  $\mathcal{B}(n, t) = \{u \in (\mathbb{F}_2)^n \mid w(u) = t\}$ , with cardinality

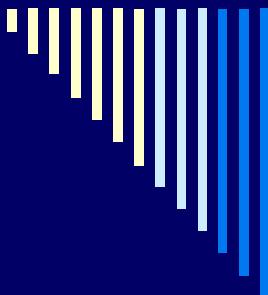

$$r = \binom{n}{t} \approx \frac{n^t}{t!}$$

- A *ranking function* is a mapping  $rank: \mathcal{B}(n, t) \rightarrow \{1\dots r\}$  which associates a unique index in  $\{1\dots r\}$  to each element in  $\mathcal{B}(n, t)$ . Its inverse is called the *unranking function*.
- Rank size:  $\lg r \approx t(\lg n - \lg t + 1)$  bits.

# Ranking and Unranking Permutations

- Ranking and unranking can be done in  $O(n)$  time (Ruskey 2003, algorithm 4.10).
- Computationally simplest ordering: colex.
- Definition:  $a_1a_2\dots a_n < b_1b_2\dots b_m$  in colex order iff  $a_n\dots a_2a_1 < b_m\dots b_2b_1$  in lex order.

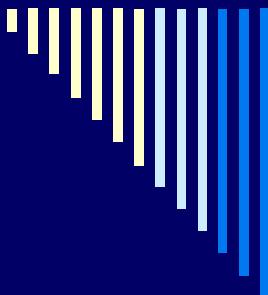

# Colex Ranking

- Sum of binomial coefficients:

$$Rank(a_1 a_2 \dots a_k) = \sum_{j=1}^k \binom{a_j - 1}{j}$$

- Implementation strategy: precompute a table of binomial coefficients.

# Colex Unranking

```
for  $j \leftarrow k$  downto 1 {
```

```
     $p \leftarrow j$ 
```

```
    while  $\binom{p}{j} \leq r$  {
```

```
         $p \leftarrow p + 1$ 
```

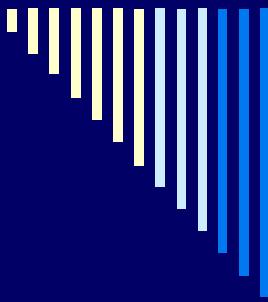

```
    }
```

```
     $r \leftarrow r - \binom{p-1}{j}$ 
```

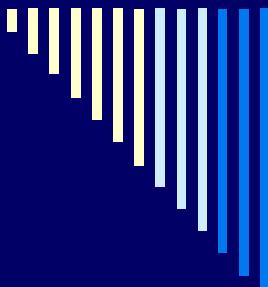

```
     $a_j \leftarrow p$ 
```

```
}
```

```
return  $a_1 \ a_2 \dots \ a_k$ 
```

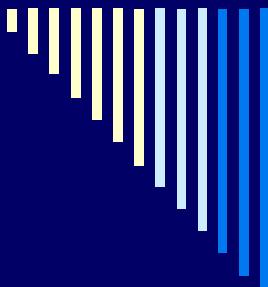

# Appendix C

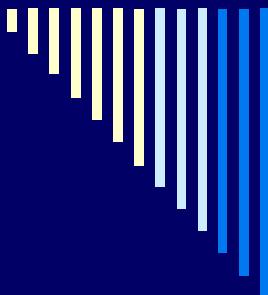

# Decoding a syndrome $s(x)$ for a binary Goppa code

```
v(x) ← (x + 1/s(x))1/2 mod g(x) // extended Euclid!
F ← v, G ← g, B ← 1, C ← 0, t ← deg(g)
while (deg(G) > ⌊t/2⌋) {
    F ↔ G, B ↔ C
    while (deg(F) ≥ deg(G)) {
        j ← deg(F) – deg(G), h ← Fdeg(F) / Gdeg(G)
        F ← F – h xj G, B ← B – h xj C
    }
    σ(x) ← G(x)2 + xC(x)2
    return σ // error locator polynomial
```

# Appendix D

# Decoding Alternant Codes

- Similar to Patterson's algorithm for binary irreducible Goppa codes.
- Extended Euclid initialized with  $s(x)$  instead of  $v(x)$  and  $x^r$  instead of  $g(x)$ .
- $\sigma(x) = b(x)/b(0)$  (so that  $\sigma(0) = 1$ ).
- N.B.: Patterson's algorithm works for binary reducible Goppa codes as long as the syndrome is invertible mod  $g(x)$ .
